Investigating the antecedents of general purpose technologies: A patent perspective in the green energy field

Abstract

This research analyzes the emergence of general purpose technologies. Specifically, we examine the relationship between how broadly organizations search across diverse knowledge domains in the invention process (i.e., their search breadth) and the technological generality of resulting inventive outcomes. Based on a sample of 88,748 patents belonging to the "Alternative energy production" and "Energy conservation" classes, we reveal that search breadth is curvilinearly related to an invention's technological generality. Furthermore, we assess if a geographically dispersed inventive team moderates the costs and benefits of searching broadly, showing that it makes organizations more able to benefit from a wider search breadth.

Keywords: general purpose technologies; search breadth; geographically dispersed teams; green energy technologies

1. Introduction

General purpose technologies (GPTs) refer to technologies “the exploitation of which will yield benefits for a wide range of sectors of the economy and/or society” (Keenan, 2003:132), such as the steam engine, nanotechnology, and the ICT (Banerjee and Cole, 2010; Bresnahan and Trajtenberg, 1995; Shea, 2005). This characteristic is ascribed to their high level of technological generality, which indeed favors their use and spread in a broad range of industries and market applications (Bresnahan and Trajtenberg, 1995; Gambardella and Giarratana, 2013; Keenan, 2003; Thoma, 2009). GPTs have gained more and more attention across both academics and practitioners in the last years. Nevertheless, as stated by Thoma (2009:108), “our understanding of GPTs is still

1
2
3
4 somewhat limited”, hence requiring more in-depth studies on how they work and emerge.
5
6 Particularly, this article attempts to shed more light on the emergence of GPTs.
7

8
9 Previous research has argued that the ability to develop more generic technologies is associated
10 to the use of diverse technological fields in the inventing activities (eg., Argyres and Silverman,
11 2004; Hicks and Hegde, 2005), which in turn increases the probability to make the resulting
12
13 inventions applicable in diverse industrial contexts (Banerjee and Cole, 2010). This drives us to the
14
15 research question of the present study, as what are the effects of a firm’s strategy to search for
16
17 knowledge across a broad range of technological domains on the creation of a GPT? Indeed, among
18
19 other types of search strategy, such as search depth and search scope (eg., Katila and Ahuja, 2002),
20
21 organizations can vary the diversity of knowledge to solve a specific technical problem, by deciding
22
23 to expand the breadth of their search across diverse knowledge areas. We refer to this search
24
25 strategy as search breadth (see also Capaldo and Messeni Petruzzelli, 2011), where the more
26
27 different the knowledge areas searched across, the broader the breadth of search (Subramanian and
28
29 Soh, 2010).
30
31
32
33
34
35

36 We argue that organizations can gain from search broadly in creating generic technologies
37
38 and extend this logic by suggesting also that these benefits are subjected to decreasing and negative
39
40 returns. Specifically, we draw on theories that support the assumption that searching in diverse
41
42 technological domains improves recombination possibilities and avoids cognitive myopia (Fleming,
43
44 2001; Levinthal and March, 1993; Maggitti et al., 2013), which may lead to the creation of
45
46 technologies that more easily span industry realms. However, when the number of knowledge fields
47
48 searched across rises beyond a certain threshold, cognitive and managerial constraints related to the
49
50 ability to link them together arise (Capaldo and Messeni Petruzzelli, 2011), hence suggesting an
51
52 inverted U-shaped relationship between search breadth and technological generality. Furthermore,
53
54 since people actually lie at the core of the recombinant process characterizing organizations’
55
56 inventing activities (Fleming, 2001), we also claim that this curvilinear relationship is moderated by
57
58 the degree of geographic dispersion of the inventive team, since it may alter the threshold level of
59
60
61
62
63
64
65

1
2
3
4 search breadth at which decreasing and negative returns set in. Indeed, the past literature has argued
5
6 that organizations' learning and recombination opportunities can be influenced by pursuing a R&D
7
8 internationalization strategy, as reflected by the use of geographically dispersed teams (e.g.,
9
10 Gajendran and Joshi, 2012; Gassmann and von Zedtwitz, 2003; O'Leary and Mortensen, 2010;
11
12 Susman et al., 2003). This, in turn, depends on the possibility to tap into unique bodies of
13
14 knowledge that reside in specific geographic locations, and acquire new relational capital and
15
16 problem-solving techniques (e.g., Doz and Wilson, 2013; Gajendran and Joshi, 2012; Kratzer et al.,
17
18 2006; Singh, 2008).
19
20
21

22 The green energy sector is chosen as the research setting for the study. Indeed, related
23
24 inventions often arise from the recombination of multiple technological areas (OECD, 2012), and
25
26 their underlying knowledge is geographically dispersed (Albino et al., 2014), hence making search
27
28 breadth and team dispersion relevant factors to be taken into account. This choice, more
29
30 particularly, also follows the need to comprehend how to develop green GPTs, which has become
31
32 more and more as an urgent issue (Cecere et al., 2014; Pearson and Foxon, 2012). Accordingly, to
33
34 test our predictions, we collected 88,748 patents successfully filed at the U.S.PTO. from 1971 to
35
36 2009 and belonging to the "Alternative energy production" and "Energy conservation" green
37
38 technological classes, as identified by the International Patent Classification (IPC) Green Inventory.
39
40
41

42 The key contribution of this paper consists in empirically testing the impact of an
43
44 organization's search breadth in the invention process on the level of an invention's technological
45
46 generality, and how the internationalization of the inventive team alters the benefits of a wide
47
48 breadth of search. In addition, we focus our attention on a novel research setting, as represented by
49
50 the green energy sector, hence allowing us to shed more light on the factors favoring the
51
52 development of green GPTs in that industry.
53
54
55

56 The reminder of the paper is structured as follows. First, we provide the theoretical framework
57
58 and present the hypotheses. Then, we describe the sample and the research methodology.
59
60
61

1
2
3
4 Afterwards, we expose data analysis and results. Finally, we provide discussion and implications, as
5
6 well as limitations and directions for future research.

10 **2. Theoretical framework and hypotheses**

11 **2.1. General purpose technologies**

12
13
14
15
16
17 The idea that a technical solution can be applied across multiple domains dates back to Smith
18 (1776) in *The Wealth of Nations* and was further re-examined by Stigler (1951), who referred to it
19 as “general specialities”. More recently, instead, the literature has focused on the concept of GPTs,
20 which has captured the attention of many scholars and executives in the last two decades (e.g.,
21 Bresnahan and Trajtenberg, 1995; Gambardella and Giarratana, 2013; Keenan, 2003). With the term
22 GPTs, they mainly refer to technologies characterized by diverse technological fields, forming a
23 knowledge base “with high levels of innovative complementarities and an ever-expanding set of
24 new applications in a wide variety of industrial contexts” (Arikan, 2009:666). Indeed, a GPT is a
25 pervasive technology that allows economic agents to combine existing technical solutions of
26 different sectors with it, or build new innovative activities upon the same GPT, hence acting as a
27 platform for subsequent complementary technological developments (Bresnahan and Trajtenberg,
28 1995; Gambardella and McGahan, 2010). In turn, this complementary effect enhances the impact of
29 the GPT and helps it to drive the overall technical progress and promote economic growth
30 (Bresnahan and Trajtenberg, 1995; Helpan and Trajtenberg, 1998). Thereby, inventions can differ
31 along a particular attribute, namely technological generality (Gambardella and Giarratana, 2013),
32 which influences their breadth of impact (Argyres and Silverman, 2004; Banerjee and Cole, 2010),
33 facilitating the recombination of an invention with technologically distant components and its
34 consequent diffusion.
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57

58 Recognizing the presumed role of GPTs as “engines of growth”, past studies have been long
59 interested in the benefits and impacts of these technological solutions, thus revealing their important
60
61
62
63
64
65

1
2
3
4 role in creating value at both the microeconomic and macroeconomic level (Bresnahan and
5
6 Trajtenberg, 1995; Helpman and Trajtenberg, 1998; Rosenberg and Trajtenberg, 2004; Shane, 2004).
7
8 However, the commercialization and diffusion of GPTs are not straightforward, being principally
9
10 limited by the high adaptation efforts required to apply them in diverse industries (Gambardella and
11
12 Giarratana, 2013). Thereby, in the recent past, the literature has delved into the invention
13
14 commercialization strategies that should be adopted to make GPTs available and diffused on the
15
16 market (Gambardella and Giarratana, 2013; Gambardella and McGahan, 2010; Maine and Garnsey,
17
18 2006; Majumdar et al., 2010; Rainer and Strohmaier, 2014; Thoma, 2009). Nevertheless, only few
19
20 insights about the antecedents of GPTs have been offered (Thoma, 2009). Argyres and Silverman
21
22 (2004) first dug into this topic, proving that organizations with a centralized R&D structure, rather
23
24 than a R&D lab for each product division, create inventions that span industry realms. This is
25
26 explained by arguing that these organizations are more likely to merge different knowledge areas
27
28 into a single technology, since they manage diverse types of knowledge simultaneously (see also
29
30 Banerjee and Cole, 2010). Further, looking at the types of organization embroiled in inventive
31
32 activities, Hicks and Hegde (2005) suggested that serial technology suppliers are more able to
33
34 create GPTs. Accordingly, since their aim is to sell their inventions to as many organizations as
35
36 possible, these companies tend to create technical solutions whose knowledge base is highly
37
38 diversified, so as to allow to a number of different downstream specialized companies, both in the
39
40 same and other sectors, to understand the inventions' underlying knowledge and build on them. In
41
42 line with this reasoning, it emerges that developing technologies embodying a diversified variety of
43
44 knowledge may contribute to the emergence of GPTs. In other words, it increases inventions'
45
46 technological generality.
47
48
49
50
51
52

53
54 Moreover, an invention can be considered as the result of “a process of recombinant search
55
56 over technology landscapes” (Fleming and Sorenson, 2001:1019). Therefore, the diversity of
57
58 knowledge that is searched in the inventive activities to solve a technical problem plays a key role
59
60 in developing general technologies. In fact, it affects the variety of technological fields that will
61
62

1
2
3
4 characterize the subsequent invention (Ejeremo and Karlsson, 2006; Maggitti et al., 2013), hence
5
6 influencing the probability that a technology further spans industry boundaries and market
7
8 applications. Building on this argument, we more specifically analyze the costs and benefits of an
9
10 organization's strategy to search broadly in the invention process for the development of
11
12 technologically general inventive outcomes. Furthermore, we also investigate how these costs and
13
14 benefits may change when organizations pursue a R&D internationalization strategy, as reflected by
15
16 the decision to form a geographically dispersed inventive team. Indeed, relevant knowledge inputs
17
18 that are required to innovate in many sectors are often dispersed among diverse geographical areas
19
20 (Doz and Wilson, 2013; Singh, 2008). Thereby, distributed teams can favor the access and
21
22 acquisition of this unique body of knowledge, hence increasing the variety of the exploitable
23
24 knowledge (Chen et al., 2012; Hoegl et al., 2007). In addition, they are deemed to have better
25
26 combination capabilities and act more creatively than co-located teams, since they also tap into
27
28 foreign sources of know-how and relational capital (Gajendran and Joshi, 2012; Kratzer et al., 2006;
29
30 O'Leary and Mortensen, 2010).

31 32 33 34 35 36 37 38 **2.2. Search breadth**

39
40 It has been suggested that the more diverse the technological domains upon which an invention
41
42 is based, the higher its level of technological generality and subsequent breadth of impact (Argyres
43
44 and Silverman, 2004; Banerjee and Cole, 2010). Thus, it is reasonable to assume a positive effect of
45
46 a wide search breadth on the emergence of GPTs. Indeed, enriching the diversity of knowledge
47
48 domains in the search process increases the number of technological pieces that will characterize an
49
50 invention, as well as the potential linkages and associations between the diverse technological areas
51
52 (Capaldo and Messeni Petruzzelli, 2011; Fleming, 2001; Kauffman, 1993; Maggitti et al., 2013;
53
54 Maine et al., 2014). In addition, a broad search breadth provides stimuli for cross-fertilization of
55
56 different knowledge fields, perspectives, and ideas (Björkdahl, 2009; Hargadon and Sutton, 1997),
57
58 hence favoring the use of different knowledge pieces simultaneously and their integration into a
59
60
61
62
63
64
65

1
2
3
4 comprehensive whole. In turn, this can raise the likelihood that future technological developments,
5
6 independently from their specific industrial context, can be built on inventions arising from search
7
8 efforts spanning multiple technological boundaries. Furthermore, a wide breadth of search also
9
10 leads to the development of new problem-solving techniques (Ahuja and Lampert, 2001) and avoid
11
12 cognitive myopia toward different types of commercial application (Levinthal and March, 1993;
13
14 Novelli, Forthcoming; Rosenkopf and Nerkar, 2001). Thereby, this contributes to reduce the risks to
15
16 focus on a single market, hence increasing the probability to pursue diversified objectives at the
17
18 same time, as well as to recognize a wider variety of potential commercial opportunities that may
19
20 unfold as the different knowledge areas are searched and combined. Finally, inventions resulting
21
22 from search efforts directed toward multiple diverse technological fields can have more chances to
23
24 be understood by organizations operating in different industries, hence making these technologies
25
26 as more widely used in many sectors (Banerjee and Cole, 2010).
27
28
29
30

31 Although the benefits of enlarging the breadth of search across several technological
32
33 domains for the development of GPTs can be considerable, there is a point where this search effort
34
35 is subjected to diminishing or even negative returns. Searching across a wide range of knowledge
36
37 domains extensively can in fact limit the creation of more generic solutions. At some point,
38
39 organizations' cognitive capabilities required to find and create useful knowledge combinations
40
41 drastically drop, due to the increasing probability to work with unfamiliar knowledge domains and
42
43 the lack of the required absorptive capacity (Cohen and Levinthal, 1990; Laursen and Salter, 2006).
44
45 Hence, also the organizations' ability to recognize the technological and market potential of the
46
47 diverse knowledge diminishes (Lin and Chang, Forthcoming). This may thus reduce the likelihood
48
49 to come up with a discovery of more generalizable impacts. In addition, as search breadth becomes
50
51 wider, the probability to conceive too many ideas respect to organizations' ability to select and
52
53 implement them grows (Capaldo and Messeni Petruzzelli, 2011; Koput, 1997). Thereby, they might
54
55 then focus on a restricted set of more familiar knowledge pieces in order to limit the number and
56
57 complexity of the potential knowledge combinations (Fleming, 2001), hence reducing the diversity
58
59
60
61
62
63
64
65

1
2
3
4 of the knowledge base characterizing inventive outcomes. Furthermore, organizations tend to
5
6 conduct their search processes in a path-dependent way, which are often characterized by a well-
7
8 established modus operandi (Nelson and Winter, 1982; Peteraf, 1993). However, since expanding
9
10 the search breadth needs the creation of new routines with the aim to integrate multiple knowledge
11
12 areas, they often face managerial constraints in performing such a task, hence limiting the effective
13
14 use and integration of a diversified knowledge stock (Capaldo and Messeni Petruzzelli, 2011;
15
16 Nelson and Winter, 1982). Finally, searching broadly comes with uncertainties regarding the future
17
18 value of the inventions (Messeni Petruzzelli et al., Forthcoming; Taylor and Greve, 2006). Thus,
19
20 economic agents' capacity to assess their worthiness, which is a central prerequisite to make a
21
22 technology exploited and applied across several economic sectors (Banerjee and Cole, 2010; Nelson
23
24 and Winter, 1977), is hampered. Therefore, on the basis of the above reasoning, we posit the
25
26 following hypothesis:
27
28
29
30
31
32

33
34 *Hypothesis 1. An organization's search breadth has a curvilinear (inverted U) effect on the level of*
35
36 *technological generality of the resulting invention.*
37
38
39

40 **2.3. Team geographic dispersion and search breadth**

41
42 We argue that organizations relying upon a geographically dispersed team of inventors have a
43
44 better chance of benefiting from a wider search breadth. First, the diverse knowledge inputs and
45
46 resource endowments that an organization can search across often reside and develop in different
47
48 regional clusters, such as Silicon Valley for microelectronics and Detroit for automotive equipment
49
50 (Doz and Wilson, 2013; Myles et al., 2000). Thereby, establishing dispersed teams lets
51
52 organizations get closer to these different locations in order to actually understand and acquire the
53
54 various specific bodies of knowledge (Gassmann and von Zedtwitz, 2003; Hsu et al., Forthcoming;
55
56 Singh, 2008; Penner-Hahn and Shaver, 2005). In fact, these different knowledge is usually not
57
58 easily transferable across geographic regions unless organizational R&D members “participate in
59
60
61
62
63
64
65

1
2
3
4 locale-specific practices” (Sole and Edmondson, 2002:S17; see also Singh, 2008). Accordingly,
5
6 dispersed teams may increase the organizations’ absorptive capacity and reduce the extent of coping
7
8 with unfamiliar knowledge when they search broadly. This may also alleviate the problems related
9
10 to the recognition of the technological and market potential of the diverse knowledge searched
11
12 across, hence favoring its integration and use for multiple commercial opportunities. Second, the
13
14 internationalization of the inventive team can also help organizations to identify and implement
15
16 potential relevant ideas, without reducing the diversity of the knowledge domains recombined to
17
18 develop a given invention. Indeed, members at different sites, besides having a better chance to
19
20 understand a particular piece of knowledge, acquire new problem-solving approaches and relational
21
22 capital, which allow them to generate more higher quality solutions to address a technical problem
23
24 (Edmondson and Nembhard, 2009; Gajendran and Joshi, 2012). In turn, this also helps them to
25
26 perform more creatively, and so come up with more ideas for knowledge combination (Gajendran
27
28 and Joshi, 2012; Polzer et al., 2006). Thereby, the cognitive limitations related to the integration of
29
30 different technological domains can be mitigated. Third, in an internationalized context, interactions
31
32 between team members are more spontaneous and characterized by variance in relational patterns
33
34 (Hinds and Mortensen, 2005), which let organizations using dispersed teams develop “R&D
35
36 capabilities through improvisational learning” (Parida et al., 2013:46). Thus, they are less subject to
37
38 the managerial and coordination difficulties that arise from the need to create ad-hoc routines for
39
40 favoring the exchange and integration of the various knowledge pieces in the invention process.
41
42 According to the foregoing discussion, we hypothesize:
43
44
45
46
47
48
49
50
51

52 *Hypothesis 2. Team internationalization moderates the relationship between search breadth and the*
53 *level of technological generality of an invention, such that the threshold level of search breadth at*
54 *which diminishing or negative returns arise will be higher for those organizations that use a*
55 *geographically dispersed team.*
56
57
58
59
60
61

1
2
3
4 **3. Data and methods**
5
6
7

8 **3.1. Industry setting**
9

10 The green energy sector serves as the research setting for the study. We believe this is an
11 appropriate setting because, first, the need to favor the shift toward more efficient low-carbon
12 energy systems in many sectors of the society, while promoting economic growth, is more and more
13 recognized as a an urgent issue. Hence, the relevance of green GPTs in the energy field, such as the
14 case of insulation technologies (Sorrell, 2007), have drastically risen (Cecere et al., 2014; Pearson
15 and Foxon, 2012). Second, technological developments in the green energy sector include solutions
16 having origins in diverse industries (OECD, 2012). Therefore, the extent of different technologies
17 that can be potentially recombined within the invention process is various, thus making the search
18 effort toward diverse knowledge domains as an important factor to be considered. Third, the
19 technical knowledge underlying the development of green energy technologies is dispersed among
20 many countries (Albino et al., 2014). Thereby, employing a R&D internationalization strategy is
21 seen as an effective way to tap into new knowledge and skills to develop green technical solutions
22 (Wagner, 2007). Finally, intellectual property protection is of foremost importance in the green
23 energy sector (OECD, 2012). Thereby, patents serve as appropriate proxies to capture the
24 technological inventions developed in this field.
25
26
27
28

45
46
47 **3.2. Sample and data**
48

49 Following previous studies (e.g., Albino et al., 2014; Kemp and Pearson, 2008; Popp, 2006),
50 we use patent data in order to identify inventions developed in the green energy sector. In particular,
51 we refer to the IPC Green Inventory for patent collection (Albino et al., 2014; Shapira et al., 2014).
52 It is a well-defined classification that was developed by an IPC Committee of experts working for
53 the World Intellectual Property Organization in 2008. Specifically, the IPC Green Inventory allows
54 to search for patents related to the so called Environmentally Sound Technologies (ESTs), as
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 defined in the Chapter 34 of the Agenda 21 (UN, 1992), by suggesting specific IPC codes for patent
5
6 retrieval. Specifically, seven green technological classes were taken into account, in turn divided
7
8 into a hierarchical set of subclasses¹. For the purpose of this study, we limit our attention to the
9
10 “Alternative Energy Production” and “Energy Conservation” classes. Hence, we collected all the
11
12 patents successfully filed at the U.S.PTO. from 1971 to 2009 that refer to the two green
13
14 technological classes above mentioned. For each patent we then gathered bibliographic information
15
16 (i.e., backward, forward, and scientific-based citations, as well as information about the inventing
17
18 team and assignees). Being primarily interested in the search efforts undertaken by a given
19
20 organization, we limit our sample to those patents registered by just one assignee, leaving out
21
22 patents owned by individuals working autonomously, as well as those granted to more than one
23
24 organization in order to avoid network-specific effects. This procedure yielded a final sample of
25
26
27
28
29 88,748 patents.
30
31
32

33 **3.3. Measures**

34 **3.3.1. Dependent variable**

35
36
37
38 *Technological generality.* Following previous studies (e.g., Argyres and Silverman, 2004; Banerjee
39
40 and Cole, 2010; Gambardella and Giarratana, 2013; Hicks and Hegde, 2005), in order to
41
42 operationalize technological generality we refer to the generality index proposed by Hall et al.
43
44 (2001). In particular, this refers to a Herfindhal-type index that measures the diversity of the
45
46 technological classes assigned to patents that cite a focal one. The rationale behind this index is that
47
48 the higher the variety of technological classes of the citing patents, the higher the focal patent’s
49
50 technological generality. On the contrary, if citing patents are concentrated in few technological
51
52 fields, the focal patent’s technological generality is low. However, this measure has been revealed
53
54 to be biased downward when the number of forward citations is rather small (Hall, 2005; Hall et al.,
55
56
57
58
59
60

61 ¹ See <http://www.wipo.int/classifications/ipc/en/est/>

1
2
3
4 2001). Hence, we correct this measure according to Hall (2005), who suggested to multiply the
5
6 generality index by the ratio of the number of forward citations received by a focal patent (F_P) over
7
8 F_P minus one. Therefore, our measure of technological generality is computed as follows:
9

$$10 \quad \text{Technological generality} = \frac{F_P}{F_P - 1} [1 - \sum (\frac{F_{iP}}{F_P})^2],$$

11
12
13 where F_{iP} stands for the number of citations received by the focal patent P in the three digit U.S.
14
15 class i.
16
17

18 19 20 **3.3.2. Independent and moderating variables**

21
22 *Search breadth.* To compute this variable we follow the measure of originality, as defined by Hall
23
24 et al. (2001) (see also Capaldo and Messeni Petruzzelli, 2011; Messeni Petruzzelli et al.,
25
26 Forthcoming). It is based on the same rationale of the generality measure, except for the fact that it
27
28 refers to a focal patents' backward citations. Thus, the more diverse the extent of technological
29
30 classes assigned to the patents cited by a focal one, the wider is assumed to be the breadth of search
31
32 (Capaldo and Messeni Petruzzelli, 2011). Specifically, search breadth is operationalized as follows:
33
34
35

$$36 \quad \text{Search breadth} = 1 - \sum (\frac{B_{iP}}{B_P})^2,$$

37
38
39 where B_{iP} is the number of citations made by the focal patent P belonging to the three digit U.S.
40
41 class i, and B_P is the total number of backward citations of the focal patent P.
42
43
44

45
46 *Team dispersion.* Patent documents report information about the team involved in the creation of a
47
48 given invention. Particularly, for each inventor it is indicated the name and where he/she resides.
49
50 Based on this data, according to previous studies (e.g., Lahiri, 2010; Nielsen, 2010), we
51
52 operationalize the dispersion of the inventive team as follows:
53
54
55

$$56 \quad \text{Team dispersion} = 1 - \sum (\frac{T_{cP}}{T_P})^2,$$

57
58
59 where T_{cP} is the number of inventors being part the inventing team of the focal patent P that resides
60
61 in the country c, and T_P is the total number of inventors of the focal patent P.
62
63
64
65

3.3.3. Control variables

Other factors can influence the level of technological generality of an invention. Therefore, control variables are also included in our model. First, we consider the size of the inventive team (*Team size*). It is measured by counting the number of people reported as inventors in the patent document (Singh, 2008). Second, we control for the total number of backward citations made by a focal patent (*Cited*) (Banerjee and Cole, 2010). Third, we include the number of claims, as reported in the patent document (*Claims*) (Tong and Frame, 1994). Fourth, the use of scientific knowledge in the invention process is also taken into account, by measuring the number of references made by a patent to non-patent literature (Narin et al., 1997). Fifth, to account for potential time effects, we include a set of three dummy variables to reflect four important time periods that have characterized the green energy sector (*dummy period*). Specifically, the first time period ranges from the 1971 to the 1987, year in which the Brundland report was published (WCED, 1987). The second one refers to the period between 1988 and 1997, which ends when the Kyoto protocol was signed. The third one goes from 1998 to 2002, when the Johannesburg Declaration on Sustainable Development was adopted at the World Summit on Sustainable Development (UN, 2002). The last one captures all the years after the 2002 till 2009. Sixth, we include three out of four dummy variables capturing the different types of patent assignee (*dummy assignee*), namely research centers, companies, financial institutions, and governmental organizations. Finally, in order to control for the patent's technological class, we add a dummy variable having value one if the patent belongs to the "Energy conservation" class, zero otherwise (*dummy class*).

3.4. Analysis

Since our aim is to assess the influence of an organization's breadth of search on the level of an invention's technological generality, the single patent is used as the unit of analysis. Our dependent variable assumes values that range from zero to one. In this case, a Tobit regression model is more appropriate for hypothesis testing (Banerjee and Cole, 2010). Indeed, an OLS regression may lead

1
2
3
4 to inconsistent parameter estimates, since predictions of related models can go outside the range
5
6 between our dependent variable is defined (Long, 1997; Wooldridge, 2012), hence making OLS
7
8 less than ideal. In other words, it does not approach the "true" population parameters (Long, 1997).
9

10 11 12 13 **4. Results** 14

15 Table 1 shows descriptive statistics and pairwise correlations, presenting values below the 0.70
16
17 threshold (Cohen et al., 2013), hence limiting multicollinearity concerns. Results of the Tobit
18
19 regression models are presented in Table 2. Model 1 is the baseline model and includes the control
20
21 variables only. Model 2 is used to test Hypothesis 1 and includes search breadth as linear and
22
23 quadratic terms. Finally, Model 3 includes the moderator and its interactions with the linear and
24
25 squared term of search breadth.
26
27

28
29 The baseline model shows that enlarging the dimension of the inventing team leads to more
30
31 general solutions, being the coefficient of *Team size* positive and significant ($\beta = 0.021, p < 0.001$).
32
33 Similarly, an invention's technological generality increases with the number of citations made to
34
35 previous patents ($\beta = 0.002, p < 0.001$) and with the number of claims ($\beta = 0.002, p < 0.001$). On
36
37 the contrary, it decreases with the reliance on basic research ($\beta = -0.001, p < 0.001$).
38
39

40
41 Hypothesis 1 posits an inverted U-shaped relation between the breadth of search and the level
42
43 of technological generality of an invention. Our results support this prediction. Indeed, estimates of
44
45 Model 2 show that the linear term of *Search breadth* is positive and significant ($\beta = 0.401, p <$
46
47 0.001), while its squared term is negative and significant ($\beta = -0.249, p < 0.001$). Using the
48
49 coefficient estimates of Model 2 (Zelner, 2009) we also graph the search breadth against the
50
51 predicted level of technological generality (Figure 1), providing further support to our hypothesis.
52
53 The inflection point beyond which the impact of search breadth decreases technological generality
54
55 corresponds to a value of 0.807.
56
57
58
59
60
61
62
63
64
65

1
2
3
4 Our second hypothesis refers to the moderation effect of *Team dispersion*. Consistent with
5
6 Hypothesis 2, both the interaction terms with the linear and squared term of *Search breadth* are
7
8 significant and in the expected directions ($\beta = 0.574, p < 0.001$ and $\beta = -0.567, p < 0.01$,
9
10 respectively). To gain further insight into the interaction effects predicted by Hypotheses 2, we
11
12 decompose the interaction terms and conduct simple slope analysis. We consider two levels of the
13
14 moderating variables - low (one standard deviation below the mean) and high (one standard
15
16 deviation above the mean) - and estimate the effect of *Search breadth* on *Technological generality*
17
18 for both levels (Hoetker, 2007; Lahiri, 2010; Poppo et al., 2008). We plot search breadth against the
19
20 predicted level of technological generality of an invention at both low and high level of *Team*
21
22 *dispersion* (Figure 2), and compute the maximum of the two resulting inverted curves. Figure 2
23
24 shows that when the level of *Team dispersion* is low decreasing and negative returns to *Search*
25
26 *breadth* set in if *Technological generality* is above the value of 0.757. Differently, at the high level
27
28 of *Team dispersion* negative returns arise when *Technological generality* exceeds the value of
29
30 0.882. In other words, the maximum of the curve describing the relation between *Search breadth*
31
32 and *Technological generality* shifts to the right if organizations tend to adopt a R&D
33
34 internationalization strategy during inventing activities. This suggests that using R&D dispersed
35
36 teams amplifies the benefits of a wider breadth of search.

3
4 **5. Discussion and conclusions**
5

6 The previous literature has mainly focused on the advantages of GPTs in the economy (e.g.,
7
8 Bresnahan and Trajtenberg, 1995; Rosenberg and Trajtenberg, 2004), as well as on the
9
10 commercialization strategies that should be set to enter and diffuse them within the market
11
12 (Gambardella and Giarratana, 2013; Gambardella and McGahan, 2010). Yet, extant research has
13
14 scantly analyzed the antecedents of GPTs (Thoma, 2009). In this study, we explore the impact of an
15
16 organization’s strategy to search widely across diverse knowledge domains on the level of the
17
18 resulting invention’s technological generality, thus providing a better comprehension of the
19
20 emergence of GPTs. Furthermore, we also assess how a R&D internationalization strategy,
21
22 involving the establishment of geographically dispersed teams, moderates the costs and benefits of a
23
24 broad search breadth. Based on a sample of 88,748 patents belonging to the “Alternative energy
25
26 production” and “Energy conservation” technological classes, results indicate that when
27
28 organizations search across various knowledge domains technological generality increases,
29
30 although up to a certain threshold, thus revealing an inverted U-shaped effect. Furthermore, when
31
32 organizations’ inventive activity is dispersed across R&D teams, they are in a position to derive
33
34 greater benefit from a wider search breadth.
35
36
37
38
39

40 The implications for theory that arise from these results are threefold. First, we corroborate
41
42 findings of previous research on the emergence of GPTs, which argues that expanding the
43
44 knowledge base charactering an invention increases its breadth of impact in diverse industrial
45
46 contexts (Argyres and Silverman, 2004; Hicks and Hegde, 2005). Indeed, searching broadly across
47
48 multiple technological domains helps organizations in creating a wider knowledge base (Capaldo
49
50 and Messeni Petruzzelli, 2011; Maine et al., 2014). Moreover, it also provides advantages such as
51
52 the reduction of cognitive myopia, increasing recombination possibilities, and the incentive to
53
54 cross-fertilize different market ideas (e.g., Björkdahl, 2009; Maggitti et al., 2013). Furthermore, we
55
56 add to previous research by arguing that there exists a threshold level, after which a wide search
57
58 breadth comes with decreasing or even negative returns. In fact, the cognitive and managerial
59
60
61
62
63
64
65

1
2
3
4 limitations related to the management of a too wide body of knowledge, as represented by the lack
5
6 of absorptive capacity, the unfamiliarity with all knowledge domains, and the necessity to
7
8 coordinate knowledge integration, cannot be underestimated (e.g., Capaldo and Messeni Petruzzelli,
9
10 2011). Second, our study further advances our understanding of how to create GPTs when
11
12 organizations span multiple knowledge domains. Particularly, we demonstrate that in order to
13
14 relieve the diminishing and negative returns of a wide search breadth a R&D internationalization
15
16 strategy allows to alleviate organizations' cognitive and managerial limitations (Gajendran and
17
18 Joshi, 2012). Accordingly, it favors a better understanding of the diverse knowledge pieces and the
19
20 acquisition of new problem-solving techniques, which in turn enhances team members' creativity
21
22 (Hinds and Mortensen, 2005). Furthermore, it also encourages spontaneous interactions between
23
24 members, hence reducing the need to create ad-hoc routines for knowledge exchange. Third, ESTs
25
26 in the energy sector have been deemed to play an important role for enhancing economic growth
27
28 and environmental performance in several industries (Albino et al., 2014; Malek et al., 2014;
29
30 Suzuki, Forthcoming). Nevertheless, while promising, these technological solutions faced several
31
32 difficulties in diffusing on the market and failed to replace current carbon-based systems (Olson,
33
34 2014). Thereby, developing green energy technologies that can be more easily adopted and diffused
35
36 in different industry domains has been recognized as a relevant issue (Suzuki, Forthcoming).
37
38 Accordingly, our results contribute to this debate, revealing how it is possible to create green GPTs
39
40 in the energy sector (Cecere et al., 2014; Pearson and Foxon, 2012).
41
42
43
44
45
46

47 Findings of this study inspire also some managerial implications. First, managers are
48
49 advised of the double-edge word of a wide search breadth for the development of GPTs. Thereby,
50
51 we suggest balancing the search efforts toward a wide range of knowledge domains, in order to
52
53 avoid the risks to incur in the inability to gain returns from those efforts. Second, establishing
54
55 dispersed teams may reduce the problems organizations face when they search broadly, being these
56
57 useful to support the acquisition and integration of a diversified body of knowledge. Third, given
58
59 the ever increasing need to develop more green general solutions (Cecere et al., 2014), our findings
60
61
62
63
64
65

1
2
3
4 guide organizations to focus on the conditions that are most critical for creating green GPTs in the
5
6 energy field.
7

8
9 Of course, this study presents some limitations that may however lead to new interesting
10 lines of inquiry. We only consider organizations' search breadth. Other search strategies, such as
11 search scope and search depth (Katila and Ahuja, 2002) may be investigated. Furthermore,
12
13 additional characteristics of the inventive team, besides their internationalization, can be considered.
14
15 For instance, future studies may take into account the presence of star scientists, whether team
16
17 members have repeated experiences within the same group, and the set of norms characterizing
18
19 team activities (e.g., Mathieu et al., 2013). We limit our attention to inventions developed by a
20
21 single organization. Analyzing potential network-specific effects on the emergence of GPTs also
22
23 require more in depth studies. Finally, this study has the green energy sector as its research setting.
24
25
26
27 Further research considering other sectors may be useful to provide further support to our findings.
