## Abstract

The acoplanar photon pairs produced in the reaction  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  are analysed in the  $700 \text{ pb}^{-1}$  of data collected by the ALEPH detector at centre-of-mass energies between 183 and 209 GeV. No deviation from the Standard Model predictions is seen in any of the distributions examined. The resulting 95% C.L. limits set on the anomalous QGCs,  $a_0^Z$ ,  $a_c^Z$ ,  $a_0^W$  and  $a_c^W$ , are  $-0.012 < a_0^Z/\Lambda^2 < +0.019 \text{ GeV}^{-2}$ ,  $-0.041 < a_c^Z/\Lambda^2 < +0.044 \text{ GeV}^{-2}$ ,  $-0.060 < a_0^W/\Lambda^2 < +0.055 \text{ GeV}^{-2}$ ,  $-0.099 < a_c^W/\Lambda^2 < +0.093 \text{ GeV}^{-2}$ , where  $\Lambda$  is the energy scale of the new physics responsible for the anomalous couplings.

## 1. Introduction

Multiphoton production has been already investigated with the ALEPH detector to search for physics beyond the Standard Model [1]. In this Letter, acoplanar photon pairs from the reaction  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  are used to set limits on anomalous quartic gauge couplings. Quartic gauge couplings (QGCs) between the electroweak vector bosons are predicted by the Standard Model (SM), as a consequence of the  $SU(2) \times U(1)$  non-Abelian gauge structure. The SM QGC contributions are unobservably small at LEP2 energies. For example the contribution of the  $WW\gamma\gamma$  vertex (Fig. 1) to the  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  process is only a few fb [2,3]. The  $ZZ\gamma\gamma$  vertex is absent in the SM at tree level. Therefore evidence of QGCs at LEP2 would be an indication of new physics. The values of the QGCs depend strongly on the electroweak symmetry breaking mechanism. Several alternatives to the SM predict anomalous QGCs without altering the SM values of the triple gauge couplings [4,5].

The parametrization of QGCs adopted in this Letter follows the convention of Ref. [2]. The relevant C, P and CP conserving anomalous QGC contributions, not related to a TGC counterpart, are described by two additional dimension-six terms in the Lagrangian:

$$L_6^0 = -\frac{e^2}{16} \frac{a_0}{\Lambda^2} F^{\mu\nu} F_{\mu\nu} \overrightarrow{W}^{\vec{\alpha}} \cdot \overrightarrow{W}_{\vec{\alpha}},$$

$$L_6^c = -\frac{e^2}{16} \frac{a_c}{\Lambda^2} F^{\mu\alpha} F_{\mu\beta} \overrightarrow{W}^{\vec{\beta}} \cdot \overrightarrow{W}_{\vec{\alpha}}$$

with usual notations for the electromagnetic and weak fields, and where  $\Lambda$  represents the scale of the new physics responsible for the anomalous contributions. Both  $a_0$  and  $a_c$  are equal to zero in the Standard Model. In the following, the two sets of couplings,  $(a_0^W, a_c^W)$  and  $(a_0^Z, a_c^Z)$ , are assumed to be independent, as suggested in Ref. [6].

Fig. 1. Diagrams with quartic gauge couplings contributing to the  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  channel.

## 2. The ALEPH detector and event selection

### 2.1. The ALEPH detector

The ALEPH detector and its performance are described in detail in [7,8]. The analysis presented here depends mainly on the performance of the electromagnetic calorimeter (ECAL). The ECAL is a lead/wire chamber sampling calorimeter of 22 radiation length thickness. It consists of 36 modules, twelve in the barrel and twelve in each endcap, which provide coverage in the angular range  $|\cos\theta| < 0.98$ . The insensitive region between modules represents 2% of the barrel and 6% of the endcap areas. Cathode pads associated with each layer of the wire chambers are connected to form projective towers, each subtending approximately  $0.9^\circ \times 0.9^\circ$ , read out in three segments in depth (“storeys”). This high granularity provides excellent identification of photons. The energy calibration of the ECAL is obtained from Bhabha events,  $e^+e^- \rightarrow \gamma\gamma$  events and events from two-photon interactions,  $\gamma\gamma \rightarrow e^+e^-$ . The energy resolution for isolated photons is  $\sigma(E)/E = 0.18/\sqrt{E} + 0.009$  ( $E$  in GeV). The ECAL also provides a measurement of the event time  $t_0$  relative to the beam crossing with a resolution better than 15 ns for showers with energy greater than 1 GeV.

The hadron calorimeter (HCAL) and the luminosity calorimeters extend the coverage to 34 mrad from the beam axis. Together with external muon chambers, they are used in this analysis mainly to veto events in which photons are accompanied by other energetic particles. The tracking system provides efficient reconstruction of isolated charged particles in the angular range  $|\cos\theta| < 0.95$ . Photon candidates are identified by an algorithm [8] which searches for local

energy maxima within clusters of ECAL storeys. The trigger most relevant for photon events is the neutral-energy trigger with a threshold of 1 GeV (2.3 GeV) in any ECAL barrel (endcap) module. The trigger efficiency for the selections described below is estimated to be at least 99.8%.

The data have been collected at centre-of-mass energies between 183 and 209 GeV. Only runs during which all tracking devices and calorimeters were in standard working conditions are selected, corresponding to a total luminosity of  $704.4 \text{ pb}^{-1}$ .

### 2.2. Monte Carlo simulation

The KK generator version 4.15 [9] is used to simulate the SM processes for the reaction  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma(\gamma)$ . It uses the YFS approach [10] to generate an arbitrary number of initial state photons. An independent generator, NUNUGPV [11], based on exact lowest order amplitudes for the production of up to three photons in the final state, modified for higher order QED effects using transverse momentum dependent structure functions, is used to reweight the events as a function of the anomalous couplings  $a_0$  and  $a_c$ . The cross sections predicted by the two generators in the absence of anomalous couplings are consistent within 1% at LEP2 energies. The simulations have been performed at eight centre of mass energies between 182.6 and 206.7 GeV, corresponding to the average energies of the data samples. For each energy, a sample of 10000 events has been generated and processed through the ALEPH simulation and reconstruction programs.

In the following sections, the missing mass ( $M_{\text{miss}}$ ) is used as a discriminant variable to set constraints on

Fig. 2. Missing mass distribution of acoplanar photon pairs selected as described in Section 2.3. Dots with error bars are the data. The two dashed lines show the predictions from the NUNUGPV Monte Carlo program for different values of the anomalous couplings  $a_0^Z$  and  $a_c^Z$ . The new physics scale  $\Lambda$  is set to the mass of the W boson.

the anomalous couplings  $a_0^Z$ ,  $a_0^W$  and  $a_c^Z$ ,  $a_c^W$ . The distribution of the missing mass is shown in Fig. 2 for the SM and for one value of  $a_0^Z$  and  $a_c^Z$ . A larger sensitivity to the  $ZZ\gamma\gamma$  vertex is expected because of the resonant nature of the relevant graph in Fig. 1.

### 2.3. Selection of events with two acoplanar high transverse momentum photons

Only events with photons having a time measurement consistent with the beam crossing time, no reconstructed charged particle tracks and total photon energy  $\sum E_\gamma < 0.5\sqrt{s}$  are considered. No more than one hit is allowed in the muon chambers, to eliminate background arising from off-momentum muons in the beam halo and cosmic rays. Beam-related background is suppressed by rejecting events with at least 0.5 GeV detected below  $14^\circ$  from the beam axis. Events with a photon acoplanarity (defined as  $180^\circ$  minus the sum of the azimuthal angles of the two photons) above  $5^\circ$  are kept, to reject the events from the QED reaction  $e^+e^- \rightarrow \gamma\gamma(\gamma)$ . Events with two and only two photon

Table 1

Number of events in the data, number of events expected from the SM, and number of events expected for  $a_0^Z = a_c^Z = 300$ . High  $E_\gamma$ : events for which the energy of the less energetic photon is  $> 0.1\sqrt{s}$ . Low  $E_\gamma$ : energy of the less energetic photon  $< 0.1\sqrt{s}$ . The new physics scale  $\Lambda$  is set to the mass of the W boson

	All	High $E_\gamma$	Low $E_\gamma$
Data events	30	10	20
Expected events (SM)	36.2	11.6	24.6
Expected events for $a_0^Z = a_c^Z = 300$ , $\Lambda = M_W$	82.1	13.1	69.0

candidates are considered. Both photons must fulfill the conditions

$$E_\gamma/\sqrt{s} > 0.025, \quad |\cos\theta_\gamma| < 0.94,$$

$$p_{T\gamma}/E_{\text{beam}} > 0.05,$$

where  $p_{T\gamma}$  is the transverse momentum of the photon with respect to the beam line. In addition, the more energetic photon must have an energy larger than  $0.2\sqrt{s}$ .

The average reconstruction efficiency of events which fulfill the above cuts is  $70.0 \pm 2.0\%$ . In the data 30 events are found, whereas 36.2 are expected from SM contributions, as summarized in Table 1. Fig. 3 shows the distribution of the photon energy, of  $|\cos\theta_\gamma|$  and of the missing mass for data, compared to the SM predictions from KK.

## 3. Results

### 3.1. Likelihood fit

For the  $ZZ\gamma\gamma$  vertex an extended 2-dimensional binned maximum likelihood fit, taking into account both normalization and shape, is performed on the  $(M_{\text{miss}}, E_\gamma)$  distribution, with 4 bins in  $M_{\text{miss}}$  as displayed on Fig. 2 and 2 bins in  $E_\gamma$  as shown in Table 1. For the  $WW\gamma\gamma$  vertex only the  $M_{\text{miss}}$  distribution is used, since the variations of  $E_\gamma$  with  $a_c^W$  and  $a_0^W$  are much weaker than for the  $ZZ\gamma\gamma$  vertex. The two pairs of QGC parameters,  $(a_0^Z, a_c^Z)$  and  $(a_0^W, a_c^W)$  are determined independently, setting the  $WW\gamma\gamma$  (respectively  $ZZ\gamma\gamma$ ) contribution to zero.

Fig. 4 shows the negative-log-likelihood curve corresponding to the fit of  $a_0^Z/\Lambda^2$  with  $a_c^Z$  set to zero, and the curve for the fit of  $a_c^Z/\Lambda^2$  with  $a_0^Z$  set to zero. Fig. 5 shows the corresponding curves for  $a_0^W/\Lambda^2$

Fig. 3. Distribution of the photon energy  $E_\gamma$ , of  $|\cos \theta_\gamma|$  (two entries per event, one for each photon) and of the missing mass (one entry per event) for the 30 events with two photons selected as described in the text (black dots). The histograms show the SM Monte Carlo predictions corresponding to the total luminosity of the experiment.

and  $a_c^W/\Lambda^2$ . Fig. 6 shows the 68% and 95% confidence level contours in the  $(a_0^Z/\Lambda^2, a_c^Z/\Lambda^2)$  and  $(a_0^W/\Lambda^2, a_c^W/\Lambda^2)$  planes from a two-parameter fit. A weak correlation between the couplings is visible in both two-dimensional likelihood functions.

### 3.2. Systematic uncertainties

The contributions to the systematic uncertainty on the determination of the couplings are summarized in Table 2.

The effect of absence of higher order electroweak corrections in the NUNUGPV generator has been determined by the authors of Ref. [9] to be around 1%. The weight calculation error (5%) includes the uncertainty on the higher order QED corrections [12] and the effect of the finite statistics of the Monte Carlo samples described in Section 2.2. The acceptance is found to be stable within 1% when the couplings are varied. Taking into account the uncertainty on the inefficiency of the cut at  $14^\circ$  described in Section 2.3, that of the cut on the number of hits in the muon chambers

Table 2

Contributions to the systematic uncertainty on the measurements of the couplings, in percent of the cross section. The statistical relative error on the measured cross section is 18%

Source of systematic uncertainty	Error (%)
Higher order corrections	1.0
Weight calculation	5.0
Acceptance	1.0
Normalization	5.0
Energy scale	negligible
Background	negligible
Total	8.0

and the 0.5% uncertainty on the luminosity, the error on the normalization is estimated to be 5%. The contribution to the background from QED events with 3 or more photons is estimated by the GGGB program [13], to be less than 0.01 events.

The total systematic error of 8% is small with respect to the 18% statistical error on the measured cross section. Its contribution is added in quadrature to the statistical component to extract the final 95% confidence level limits on the quartic gauge couplings; these limits are

$$-0.012 < \frac{a_0^Z}{\Lambda^2} < 0.019 \text{ GeV}^{-2} \quad \text{with } a_c^Z = 0,$$

$$-0.041 < \frac{a_c^Z}{\Lambda^2} < 0.044 \text{ GeV}^{-2} \quad \text{with } a_0^Z = 0,$$

$$-0.060 < \frac{a_0^W}{\Lambda^2} < 0.055 \text{ GeV}^{-2} \quad \text{with } a_c^W = 0,$$

$$-0.099 < \frac{a_c^W}{\Lambda^2} < 0.093 \text{ GeV}^{-2} \quad \text{with } a_0^W = 0.$$

The limits from the 2-parameter fit are

$$-0.020 < a_0^Z/\Lambda^2 < 0.024 \text{ GeV}^{-2},$$

$$-0.050 < a_c^Z/\Lambda^2 < 0.055 \text{ GeV}^{-2},$$

and

$$-0.075 < a_0^W/\Lambda^2 < 0.066 \text{ GeV}^{-2},$$

$$-0.121 < a_c^W/\Lambda^2 < 0.116 \text{ GeV}^{-2}.$$

## 4. Conclusions

No evidence of anomalous quartic gauge couplings in the  $ZZ\gamma\gamma$  and  $WW\gamma\gamma$  processes has been found in

Fig. 4. Likelihood curves for (a) the fit of the QGC parameter  $a_0^Z/\Lambda^2$ , the parameter  $a_c^Z$  being set to 0, and (b) the fit of  $a_c^Z/\Lambda^2$  with  $a_0^Z$  set to 0. Systematic errors are included.

Fig. 5. Likelihood curves for (a) the fit of the QGC parameter  $a_0^W/\Lambda^2$ , the parameter  $a_c^W$  being set to 0, and (b) the fit of  $a_c^W/\Lambda^2$  with  $a_0^W$  set to 0. Systematic errors are included.

the analysis of the  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  reaction in a data sample taken at energies between 183 and 209 GeV with the ALEPH detector, corresponding to an integrated luminosity of  $704.4 \text{ pb}^{-1}$ .

The 95% C.L. limits on the QGC parameters  $a_0/\Lambda^2$  and  $a_c/\Lambda^2$  from the one-parameter fit are

$$-0.012 < \frac{a_0^Z}{\Lambda^2} < 0.019 \text{ GeV}^{-2} \quad \text{with } a_c^Z = 0,$$

$$-0.041 < \frac{a_c^Z}{\Lambda^2} < 0.044 \text{ GeV}^{-2} \quad \text{with } a_0^Z = 0,$$

$$-0.060 < \frac{a_0^W}{\Lambda^2} < 0.055 \text{ GeV}^{-2} \quad \text{with } a_c^W = 0,$$

$$-0.099 < \frac{a_c^W}{\Lambda^2} < 0.093 \text{ GeV}^{-2} \quad \text{with } a_0^W = 0.$$

These limits are comparable with the ones already set by the other LEP collaborations [14–16].

Fig. 6. Two-dimensional contours for the QGC parameters: (a)  $a_0^Z/\Lambda^2$  and  $a_c^Z/\Lambda^2$  and (b)  $a_0^W/\Lambda^2$  and  $a_c^W/\Lambda^2$ . Full line: 68% C.L. contour. Dashed line: 95% C.L. contour. The cross gives the position of the best fit. Systematic errors are included.

## Acknowledgements

We thank and congratulate our colleagues in the CERN accelerator divisions for the successful operation of LEP2. We are indebted to the engineers and technicians in all our institutions for their contribution to the excellent performance of ALEPH. Those of us from non-member countries thank CERN for its hospitality and support.
